TO ALL WHOM IT MAY CONCERN:

Be it known that WE, MARTIN SCHRÖDER and MANFRED ZÄH, citizens of Germany, whose post office addresses are Anna-Herrmann-Straße 12B, 91074 Herzogenaurach, Germany; and Weichselgartenstr. 9, 91301 Forchheim, Germany, respectively, have made an invention in:

**SPEED-DEPENDENT SETPOINT CORRECTION IN ELECTRICALLY  
REGULATED SLAVE DRIVES**

of which the following is a

**SPECIFICATION**

**FIELD OF THE INVENTION**

[0001] The invention relates to a setpoint correction method and control system for an electrically controlled or regulated slave axis which, in accordance with a predefined functional relationship, follows a guide movement of a higher-order guide axis.

**BACKGROUND OF THE INVENTION**

[0002] In many industrial machines, such as packaging and textile machines or sheet-fed offset printing machines, a plurality of movements have to be carried out regularly as a function of a central guide movement. The guide movement, which is carried out

NY02:346552.1

by a guide axis, is as a rule a cyclically repeated movement, for example the rotation of an axis. One general requirement for the guide movement is that lower-order movements which are carried out by the slave axes or follower axes follow the guide movement as exactly as possible in accordance with their predefinitions.

[0003] Classically, these are carried out by means of a mechanical construction, for example by means of cam disks, as they are known, or by a cam control system. In recent times, electronically regulated drives have been used both for the guide axis and for the slave axes, and dispensing with the positive mechanical coupling. One may speak of this as an electronic transmission. The measurement of the guide axis movements is in this case mostly carried out by means of a rotary encoder. The desired angles for the regulation of the slave axes are determined as a function of the measured guide axis angles.

[0004] The illustration according to Figure 2 shows a block diagram for generating the slave axis setpoints in the conventional manner outlined. An electrically driven guide axis L\_A changes its position by assuming various position angles  $\varphi_L$ , which are registered by a rotary encoder WG. This supplies position measured values  $\varphi_{L\_meas}$ , with which a function block F is driven which describes the geometric relationship between the movements  $\varphi_{L\_meas}$  of the guide axis L\_A and the desired movements  $\varphi_{S\_sp}$  of the follower axis or slave axis S\_A. This can be carried out in the form of a mathematical function  $\varphi_{S\_sp} = f(\varphi_{L\_meas})$  or else, for example, by means of a table, in

which pairs of values are deposited which represent corresponding locational positions between the guide axis and the slave axis. Using the position setpoints  $\varphi_{S\_sp}$  generated by the function block F on the output side, the slave axis S\_A is finally driven.

[0005] Using electronic drives as described above and shown in Figure 2, the actual angles  $\varphi_{S\_act}$  of the slave axes always lag behind their setpoints  $\varphi_{S\_sp}$ , since each position control system is afflicted with a specific delay. The difference between the position setpoint  $\varphi_{S\_sp}$  and the position measured value  $\varphi_{S\_act}$  is referred to as the lag error. If, for example, a bus system is used for the transmission of the measured guide axis measured values to the slave axes, then the lag error increases again because of the transport time on the bus. The latter is also true for those slave axes which are not regulated but merely controlled.

### SUMMARY OF THE INVENTION

[0006] The object of the present invention consists in providing a setpoint correction method and a corresponding control system which effectively avoids lag errors on the part of slave axes. According to the present invention, this object is achieved for a controlled slave axis by the method described hereinabove and further by increasing a position measured value of the guide axis for driving the slave axis by a position correction value which is dimensioned proportionally to the speed of the guide axis, with this speed being assumed to be substantially constant during a data propagation time of the position measured value of the guide axis.

NY02:346552.1

[0007] For a regulated slave axis, the object of this invention is likewise achieved by the method described at the outset and further by increasing a position measured value of the guide axis for driving the slave axis by a position correction value which is dimensioned proportionally to the speed of the guide axis, wherein the speed is assumed to be substantially constant during a data propagation time of the position measured value of the guide axis and a delay of the position control system of the slave axis.

[0008] The foregoing is preferably carried out in such a way that respective position correction values are always dimensioned such that just a lag error of the slave axis is compensated. If a rotary encoder connected to the guide axis supplies guide axis angles, then the present invention is preferably carried out for a controlled slave axis by increasing the guide axis angles by respective correction angles which are proportional to the angular velocity of the guide axis and weighted with the data propagation time of the position measured value of the guide axis. The correction angles are dimensioned in accordance with the equation:

$$\varphi_{\text{corr}} = \omega_L * T_T$$

[0009] In an electrically regulated slave axis, this is carried out by increasing the guide axis angles by respective correction angles which are proportional to the angular velocity of the guide axis and weighted with the data propagation time of the position measured value of the guide axis and the delay of the position control system of the

NY02:346552.1

slave axis. The correction angles are here dimensioned in accordance with the equation:

$$\varphi_{\text{corr}} = \omega_L * (T_T + T_R)$$

[0010] In this case, it has proven to be beneficial in both cases if the angular velocity of the guide axis is determined by differentiating the guide axis angles.

[0011] A particularly preferred method according to the present invention is if the guide axis and the slave axis communicate via a bus system, with the data propagation time representing the transmission time of the position measured values of the guide axis via the data bus. Furthermore, it is preferred where the object of the invention is achieved by a control system for generating and correcting setpoints for driving a slave axis which, in accordance with a predefined functional relationship, follows a guide movement of a higher-order guide axis which is equipped with a means of registering respective position measured values of the guide axis. To effect this purpose, it is preferred to utilize a means of generating and applying position correction values to respective position measured values, it being possible for the position correction values to be determined in such a way that these are dimensioned proportionally to the speed of the guide axis. The speed of the guide axis is in this case assumed to be substantially constant during a data propagation time of the position measured value of the guide axis and/or a delay of a position control system of the slave axis.

[0012] The control system according to the present invention is distinguished, inter alia, by the fact that respective position correction values can always be determined in such a way that a lag error of the slave axis can be compensated. A particularly cost-effective embodiment of such a control system uses a rotary encoder to supply guide axis angles as the means of registering position measured values of the guide axis. It has additionally proven to be advantageous if guide axis angles registered in this way can be increased by respective correction angles which are proportional to the angular velocity of the guide axis and weighted with the data propagation time of the position measured value of the guide axis. It is possible for these correction angles to be dimensioned in accordance with the equation:

$$\varphi_{\text{corr}} = \omega_L * T_T$$

[0013] Similarly, to compensate for regulation delays, registered guide axis angles can be increased by respective correction angles which are proportional to the angular velocity of the guide axis and weighted with the delay of the position control system of the slave axis. It is possible for said correction angles to be dimensioned in accordance with the equation:

$$\varphi_{\text{corr}} = \omega_L * T_R$$

[0014] Furthermore if a means of differentiating the guide axis angles is provided, then the angular velocity of the guide axis can be derived particularly simply and effectively.

[0015] Compensating lag errors with a control system according to the present invention is suitable to a particular extent if a bus system is provided via which the guide axis and the slave axis communicate. In this case, the data propagation time then represents the transmission time of the position measured values of the guide axis via the data bus.

### **BRIEF DESCRIPTION OF THE INVENTION**

[0016] Further advantages and details of the present invention are described in the context of the preferred embodiment presented below and in conjunction with the Figures in which :

- FIGURE 1 shows a block diagram of a structure for generating slave axis setpoints with compensation according to the inventive of lag errors of the slave axis;
- FIGURE 2 shows a block diagram of a conventional structure for generating slave axis setpoints;
- FIGURE 3 shows a possible geometric relationship between a guide axis and a slave axis, using the example of a carding machine from the textile industry;

NY02:346552.1

- FIGURE 4 shows a comparison between the variation over time of the setpoint and measured value of the slave axis for the functional relationship shown in FIGURE 3, using a simulation with the conventional arrangement shown in FIGURE 2 at a guide axis rotational speed of 120 rev/min;
- FIGURE 5 shows the same comparison as in FIGURE 4 at a guide axis rotational speed of 600 rev/min;
- FIGURE 6 shows the comparison shown in FIGURE 4 at a guide axis rotational speed of 120 rev/min, but with the arrangement according to the invention according to FIGURE 1; and
- FIGURE 7 shows the comparison shown in FIGURE 5 at a guide axis rotational speed of 600 rev/min, but with the arrangement according to the invention according to FIGURE 1.

### **DETAILED DESCRIPTION OF THE INVENTION**

[0017] The present invention essentially consists in driving the slave axis with a value which indicates that the guide axis has already rotated further than is actually the case.

This can be achieved by adding a correction angle  $\varphi_{\text{corr}}$  to the measured angle  $\varphi_{L\_meas}$  of the guide axis L\_A. One difficulty is to configure the virtual onward rotation in such a way that just a lag error of the slave axis S\_A is compensated as a result.

[0018] At a low guide axis rotational speed  $\omega_L$ , a measured value transport propagation time  $T_T$ , for example on a data bus between the guide axis and the control system of the slave axis, has only a slight effect, whilst the guide axis at a high rotational speed continues to rotate through a comparatively large angle during the transport propagation time. The angular error produced in this way is:

$$\varphi_{\text{transport error}} = \int_{T_T} \omega_L dt \quad (1)$$

[0019] As a rule, the angular velocity  $\omega_L$  of the guide axis L\_A can be viewed as being approximately constant during the transport time  $T_T$ . It therefore follows that:

$$\varphi_{\text{transport error}} = \omega_L \cdot T_T \quad (2)$$

[0020] It has now been found that the angular error by which the measured guide axis angle must be increased is proportional to the angular velocity of the guide axis. Since this is similarly true for a delay  $T_R$  of a slave axis control system, the overall correction angle is given as

$$\varphi_{\text{corr}} = \omega_L \cdot (T_T + T_R) \quad (3)$$

[0021] In the case of the machine on which FIGURE 1 is based, the transport time  $T_T$  of the guide axis measured value  $\varphi_{L\_meas}$  is known. The delay time of the slave axis position control system  $T_R$  can be determined experimentally. The angular velocity

may be obtained, as discussed below, from the measured guide axis measured angle  $\varphi_{L\_meas}$  by means of differentiation. Therefore, all the variables in the above equation are known, so that the correction angle  $\varphi_{corr}$  can be calculated. The block diagram according to FIGURE 1 shows such a generation of the slave axis setpoints with the expansion according to the invention to compensate the lag error.

[0022] FIGURE 2 illustrates further elements for lag error compensation.

[0023] Before driving the unit F for describing the functional relationship between the guide axis L\_A and the slave axis S\_A, respective correction angles are added (+) to the measured position measured values  $\varphi_{L\_meas}$  in accordance with the calculation rule (3). To this end, first of all the respective position measured value  $\varphi_{L\_meas}$  is differentiated in a computing unit DIFF, by which means the corresponding angular velocity  $W_{L\_meas}$  of the guide axis L\_A is obtained.

[0024] In a multiplication unit X, this respective angular velocity is multiplied by the sum of the data propagation time  $T_T$  of the position measured value  $\varphi_{L\_meas}$  of the guide axis L\_A and the delay  $T_R$  of the position control system of the slave axis S\_A, which results in the correct correction angle  $\varphi_{corr}$ .

[0025] The illustration according to FIGURE 3 now shows, by way of example, the basic relationship between the movements of the guide axis L\_A and slave axis S\_A as a mathematical function  $\varphi_{S\_sp} = f(\varphi_{L\_meas})$  in the case of a carding machine from the

textile industry. For this purpose, the appropriate position setpoints  $\varphi_{S\_sp}$  of the slave axis are plotted against the associated position measured values  $\varphi_{L\_meas}$  of the guide axis. The result is a polynomial waveform with a number of local maxima and minima.

[0026] FIGURE 4 and FIGURE 5, the simulated variation over time resulting from the functional relationship according to FIGURE 3 is shown in the form of a comparison between slave axis setpoints  $\varphi_{S\_sp}$  and slave axis actual values  $\varphi_{S\_act}$  over time  $t$  at two constant angular velocities  $\omega_L$  for the case in which no correction of the measured guide axis angle is carried out. FIGURE 4 shows this relationship at a guide axis rotational speed  $\omega_L = 120$  rev/min, while in FIGURE 5, a guide axis rotational speed  $\omega_L = 600$  rev/min is used as a basis. It can clearly be seen that the actual value  $\varphi_{S\_act}$  is able to follow the setpoint  $\varphi_{S\_sp}$  significantly less well at the higher guide axis rotational speed, that is to say that the lag error is considerably greater.

[0027] For comparison, FIGURE 6 (guide axis rotational speed  $\omega_L = 120$  rev/min) and FIGURE 7 (guide axis rotational speed  $\omega_L = 600$  rev/min) show the same waveforms when the expansion according to the present invention is used to compensate the lag error. At both rotational speeds, the agreement between the slave axis setpoints  $\varphi_{S\_sp}$  and slave axis actual values  $\varphi_{S\_act}$  is significantly better than without the expansion according to the invention to compensate the lag error. Of particular importance is the

considerable improvement at higher rotational speeds, since the machines are operated in this range in order to achieve high productivity.
